

# An introduction to data analysis in R, and also to shark attacks

September 2019

Stefan McCabe

# What are we doing here?

This is a quick and dirty introduction to data analysis in R. The goals are to:

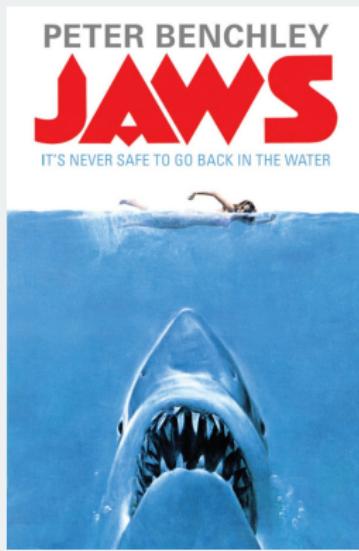

- introduce how to analyze data in R
- introduce how to visualize data in R

It is **not** anything resembling a course on statistics and data science.

I am a petty dictator, and have added some goals about things I care about:

- learn how to interpret a regression model
- learn why quantitative social scientists answer questions they way they do

# Why sharks?

# A representative article

The image shows the header of the Vox website. On the left is the Vox logo, which consists of the word "Vox" in a black serif font inside a yellow square. To the right of the logo is a horizontal navigation bar with categories: EXPLAINERS, POLITICS & POLICY, WORLD, CULTURE, SCIENCE & HEALTH, IDENTITIES, ENERGY & ENVIRONMENT, and MORE, followed by a dropdown arrow. Further to the right are icons for user profile and search.

## Two eminent political scientists: The problem with democracy is voters

Why almost everything you think about democracy is wrong.

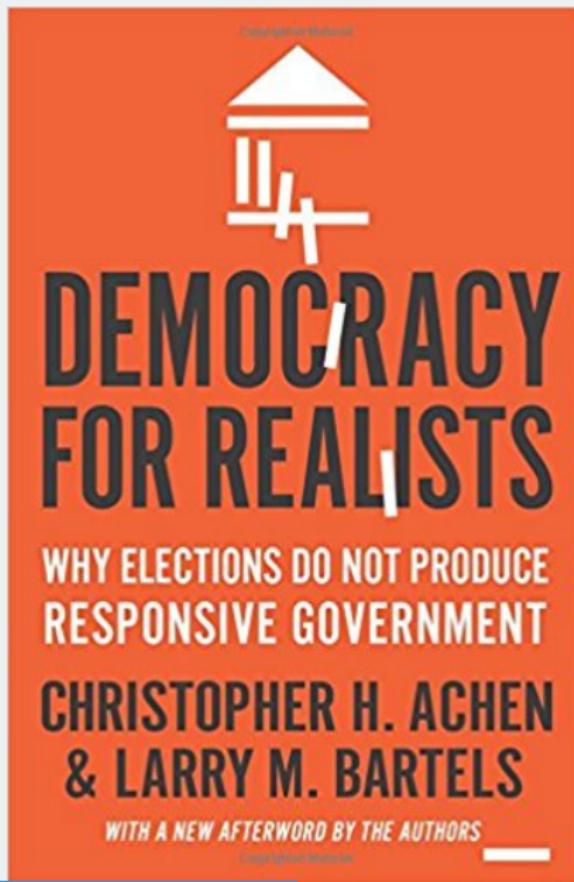

By Sean Illing | @seanilling | sean.illing@vox.com | Updated Jun 24, 2017, 12:12pm EDT

# A quote from said article

*Consider the curious case of New Jersey in 1916: That summer, there was a string of deadly shark attacks along the Jersey Shore. As a result, Woodrow Wilson lost his home state in the presidential election.*

*Why, you ask? Because the beachfront towns (which rely on tourism) were negatively impacted by the attacks. Though Wilson wasn't responsible for the hungry sharks, he was the incumbent, and people vote against incumbents when things are bad.*

# Democracy for Realists

# The Discourse I

Regardless of one's views on what the shark-attack result means for democracy, this debate is irrelevant if the empirical claim is invalid. Therefore, in this paper, we reassess the evidence that shark attacks influence presidential elections. There is virtually no compelling evidence that shark attacks influence elections, and any such effect—if it exists—must be substantively tiny. Whether or not voters are informed or competent in general, the evidence that shark attacks affect voter decisions is not nearly strong enough to generate dismay over the democratic process.

## The Discourse II

including Essex makes little difference. But we have gone over this point in some detail because it illustrates clearly the pitfalls of Fowler and Hall's approach. In their critique, the historical context, both what we wrote and what others have written, goes unmentioned or even explicitly disregarded, as if qualitative evidence were irrelevant to quantitative researchers.

That is not a recipe for good social science, and especially not for good historical research. Respect for qualitative evidence prevents many a quantitative blunder. As we will see, Fowler and Hall's arguments demonstrate over and over again how important it is to understand historical and cultural contexts and how badly quantitative researchers can go wrong when that step is skipped.

# The Discourse III

Fowler and Hall proceed by ignoring or overriding this historical evidence. But even without attention to the history, careful consideration of the quantitative evidence would have provided ample warning not to proceed as Fowler and Hall do.

# The Discourse IV

The only remaining point of disagreement is over the purported electoral effects of shark attacks in New Jersey in 1916. The evidence offered consists of two regressions with 20 and 14 non-independent observations, respectively, for which the results depend upon specification choices, a historical error, using the aberrant 1912 election to control for baseline preferences, and incorrect standard errors.

We agree with Achen and Bartels that historical context and substantive knowledge are vital for studying politics, but none of the historical facts and conjectures presented in their reply constitute persuasive evidence that shark attacks influenced elections even in this one case. Their claim that we ignore historical evidence is especially unpersuasive since it was our historical research that uncovered consequential errors in their analyses.

# Why R?

- **Pragmatism.** It's another thing you can put on your resume.
- **Interdisciplinarity.** Social scientists love R.
- **Data cleaning.** The tidyverse provides a consistent and friendly interface for data cleaning and munging.
- **Visualization.** ggplot2 is R's killer app.
- **Libraries.** Living at the cutting edge of statistical modeling? You're probably going to want to know some R.

# Preliminaries

I gave a similar but drier tutorial last year; a copy of that document is here. If you have questions about R's bizarre and terrible type system, or why there are so many <-s littered throughout the code, check it out.

# Preliminaries: Libraries

You're going to want the following libraries (hopefully already installed):

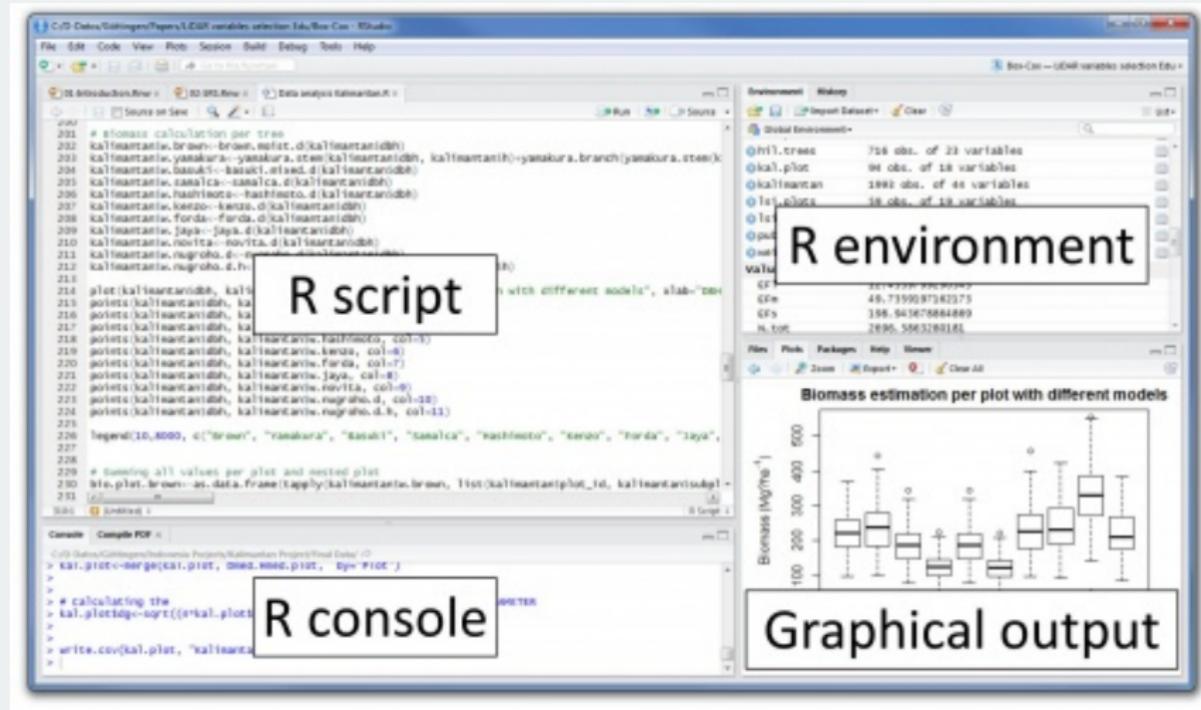

- ggplot2
- dplyr and tidyr
- readr and haven
- devtools

The tidyverse meta-package provides all the needed libraries, except for devtools.

# Preliminaries: RStudio

RStudio is the IDE for R. Accept no substitutes.

## Preliminaries: RStudio

# Preliminaries: A quick R-Python Rosetta Stone

# Locating the data

The data is taken from Fowler and Hall's critique of an earlier paper on shark attacks. I've converted their Stata files to CSV for convenience; they're on the tutorial website.

# readr

To load a data file, `readr` provides a consistent interface across formats (and if `readr` can't load it, try `haven`). Thus, we'll use the library's `read_csv` function instead of base R's `read.csv`.

(Note that `.` is valid in function and variable names in R; that is, `read.csv` is **not** a method of a class `read`.)

# Loading the sharks data

```
# sharks <- read_csv("~/git/r_tutorial_f19/resources/shark.csv")
sharks <- read_csv("https://sdmccabe.github.io/r_tutorial_f19/resources/shark.csv")

## Parsed with column specification:
## cols(
##   county = col_character(),
##   wilson1912 = col_double(),
##   wilson1916 = col_double(),
##   beach = col_double(),
##   machine = col_double(),
##   mayhew = col_double(),
##   attack = col_double(),
##   coastal = col_double()
## )
```

Note that `read_csv` treats URLs and file paths the same when reading in a file. Storing a local copy of a file is almost always preferable, but using URLs can be

# Examining the sharks data

```
dim(sharks)
head(sharks)

## [1] 21 8
## # A tibble: 6 x 8
##   county    wilson1912 wilson1916 beach machine mayhew attack coastal
##   <chr>        <dbl>       <dbl> <dbl>   <dbl>   <dbl>   <dbl>   <dbl>
## 1 ATLANTIC     0.360      0.360    1       0       0       0       1
## 2 BERGEN       0.421      0.384    0       1       0       0       1
## 3 BURLINGTON   0.413      0.426    0       0       0       0       0
## 4 CAMDEN        0.394      0.433    0       0       1       0       1
## 5 CAPE MAY     0.435      0.419    1       0       0       0       1
## 6 CUMBERLAND   0.392      0.446    0       0       0       0       1
```

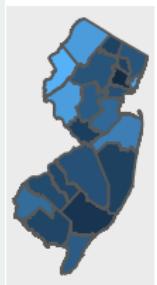

So, we have a data frame containing 21 observations of 8 attributes.

# The columns

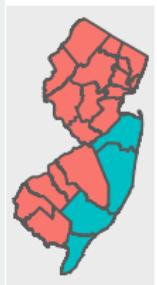

- **county**: the name of a county in New Jersey
- **wilson1912**: Woodrow Wilson's (three-party) share of the vote in 1912
- **wilson1916**: Woodrow Wilson's (two-party) share of the vote in 1916
- **beach**: does the county have substantial beach-related tourism?
- **machine**: were the politics of this county run by a political machine?
- **mayhew**: an alternative specification of machine
- **attack**: was there a shark attack in this county?
- **coastal**: is the county located on the coast?

# The columns, visualized

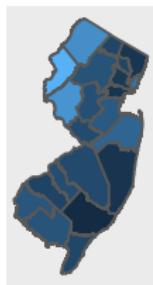

wilson1912

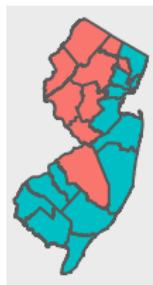

beach

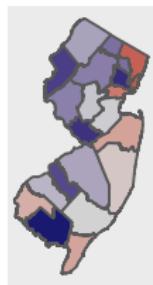

wilson1916

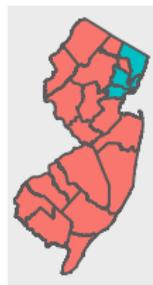

coastal

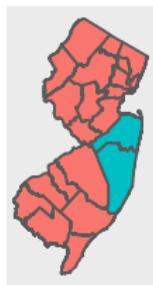

change

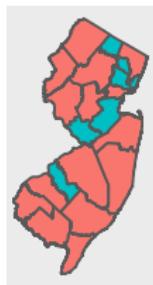

machine

attack

mayhew

# Indexing with \$

Columns of a data frame are indexed with the \$ operator, so we can pull out a single column like so:

```
sum(sharks$beach)
```

```
## [1] 4
```

There are four beach counties in New Jersey.

# Numeric indexing I

We can also use numeric indices to pull out rows or columns:

```
head(sharks[, 4]) # column indexing
```

```
## # A tibble: 6 x 1
##   beach
##   <dbl>
## 1     1
## 2     0
## 3     0
## 4     0
## 5     1
## 6     0
```

# Numeric indexing II

```
sharks[1:4,] # row indexing, plus showing 1:4 to generate a  
# sequence from 1 to 4
```

```
## # A tibble: 4 x 8  
##   county      wilson1912 wilson1916 beach machine mayhew attack coastal  
##   <chr>        <dbl>       <dbl> <dbl>    <dbl>    <dbl>    <dbl>    <dbl>  
## 1 ATLANTIC     0.360      0.360     1        0        0        0        1  
## 2 BERGEN       0.421      0.384     0        1        0        0        1  
## 3 BURLINGTON   0.413      0.426     0        0        0        0        0  
## 4 CAMDEN        0.394      0.433     0        0        1        0        1
```

This can be handy for quick and dirty operations but is less explicit than the \$ operator. Note also that **R is one-indexed.**

# Summary statistics

R has most univariate and bivariate summary statistics built in, so they can be accessed rather simply:

```
mean(sharks$wilson1912)  
cor(sharks$wilson1912, sharks$wilson1916)
```

```
## [1] 0.4386176  
## [1] 0.9121978
```

# The `summary()` function

A particularly useful function here is `summary`, which can be applied across an entire data frame:

```
summary(sharks)
```

```
##      county           wilson1912        wilson1916        beach
##  Length:21          Min.   :0.3417   Min.   :0.3601   Min.   :0.0000

```

# A cautionary tale I

Summary statistics are helpful but are no substitute for a visual understanding of a dataset. To illustrate, consider Anscombe's Quartet.

```
anscombe <- datasets::anscombe # anscombe should already be in your namespace  
# but this makes it explicit  
# note that :: pulls something from a library  
# compare to, say, the . in np.zeros()
```

# A cautionary tale II

anscombe

```
##      x1  x2  x3  x4      y1      y2      y3      y4
## 1  10  10  10   8  8.04  9.14  7.46  6.58
## 2   8   8   8   8  6.95  8.14  6.77  5.76
## 3  13  13  13   8  7.58  8.74 12.74  7.71
## 4   9   9   9   8  8.81  8.77  7.11  8.84
## 5  11  11  11   8  8.33  9.26  7.81  8.47
## 6  14  14  14   8  9.96  8.10  8.84  7.04
## 7   6   6   6   8  7.24  6.13  6.08  5.25
## 8   4   4   4  19  4.26  3.10  5.39 12.50
## 9  12  12  12   8 10.84  9.13  8.15  5.56
## 10  7   7   7   8  4.82  7.26  6.42  7.91
## 11  5   5   5   8  5.68  4.74  5.73  6.89
```

# Anscombe's summary statistics

```
round(map_dbl(anscombe[,5:8], mean), 3)
round(map_dbl(anscombe[,5:8], sd), 3)
round(map2_dbl(anscombe[,1:4], anscombe[,5:8], cor), 3)
```

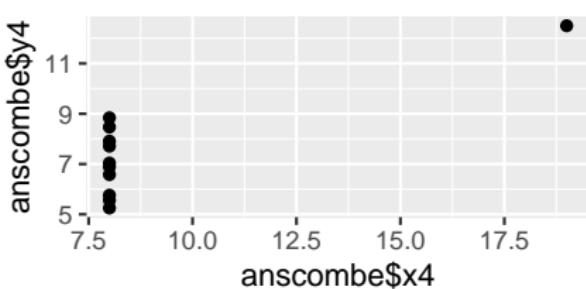

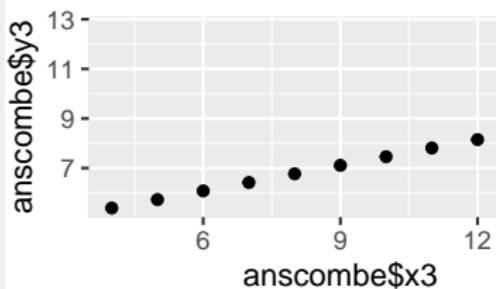

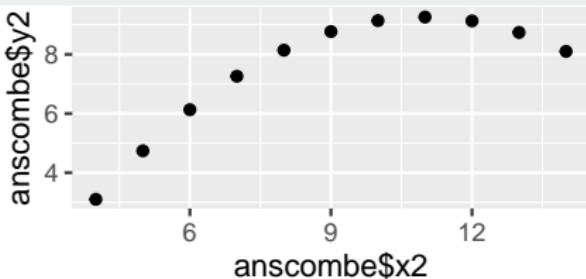

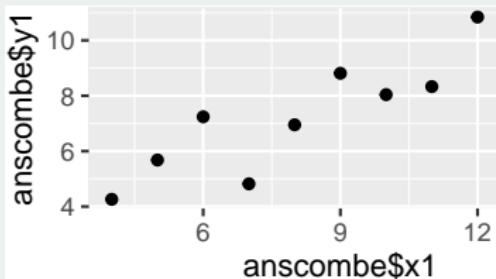

```
##      y1      y2      y3      y4
## 7.501 7.501 7.500 7.501
##      y1      y2      y3      y4
## 2.032 2.032 2.030 2.031
##      x1      x2      x3      x4
## 0.816 0.816 0.816 0.817
```

These summary statistics are quite similar...

# Anscombe visualized I

```
a1 <- qplot(anscombe$x1, anscombe$y1)
a2 <- qplot(anscombe$x2, anscombe$y2)
a3 <- qplot(anscombe$x3, anscombe$y3)
a4 <- qplot(anscombe$x4, anscombe$y4)
gridExtra::grid.arrange(a1, a2, a3, a4)
```

# Anscombe visualized II

# Anscombe visualized III

... but the underlying data are quite different. Data visualization is your friend, and one of R's strengths.

# ggplot versus “base R”

I'm deliberately omitting discussion of so-called “base R” plotting—although it is frequently useful—in favor of emphasizing `ggplot2`'s feature set. The analogy is slightly inapt, but think of `ggplot2` as playing a similar role relative to base R graphics as `seaborn` plays to `matplotlib`.

I provided some discussion of base R plotting in 2017's tutorial, so, again, check it out here.

# The structure of a `ggplot()` call

Although simple plots—scatter plots and histograms, mostly—can be generated with the `qplot` function, most of the useful visualization features require wrapping your mind around `ggplot` and its associated functions. The goal of `ggplot2` is to implement a consistent grammar of graphics, and to that end most visualizations will have the same core elements:

- a **data** frame; that is, you want to have well-structured data ahead of time
- an **aesthetic** mapping telling R which columns to include, what your x-axis is, etc.
- various **geom** or **stat** functions to turn the mapped data into visualizations

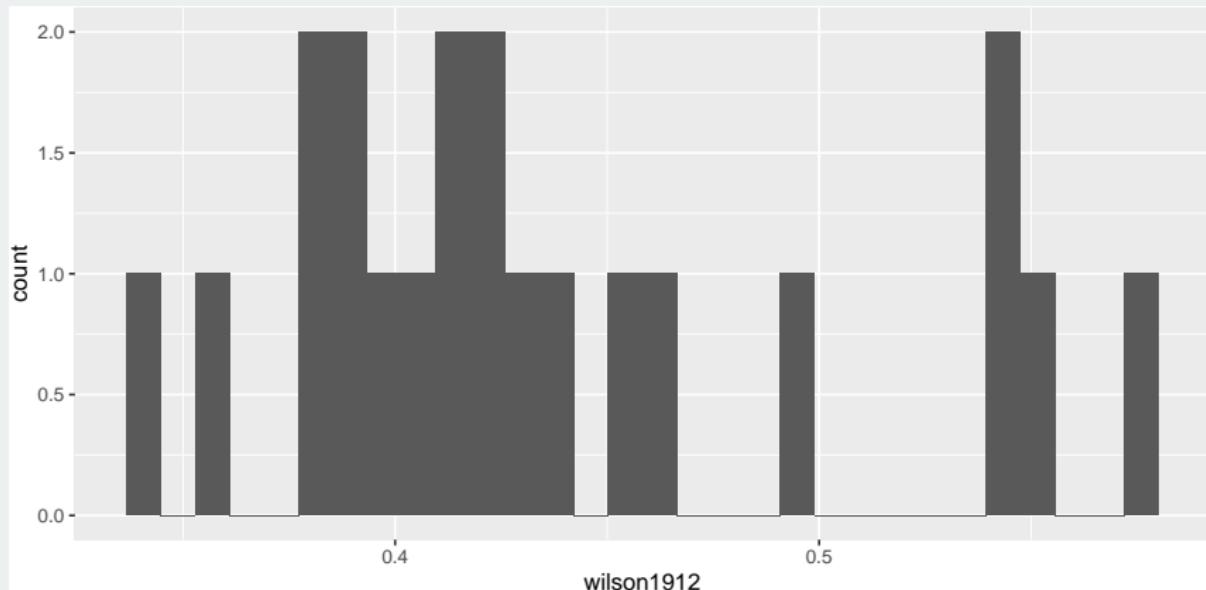

This sounds intimidating at first, but is relatively straightforward in practice. We already have the data, so once we figure out our mappings and geoms, we can make some plots.

# Histograms I

What about a histogram of Wilson's 1912 vote share?

```
ggplot(data = sharks, mapping = aes(x = wilson1912)) +  
  geom_histogram()
```

# Histograms II

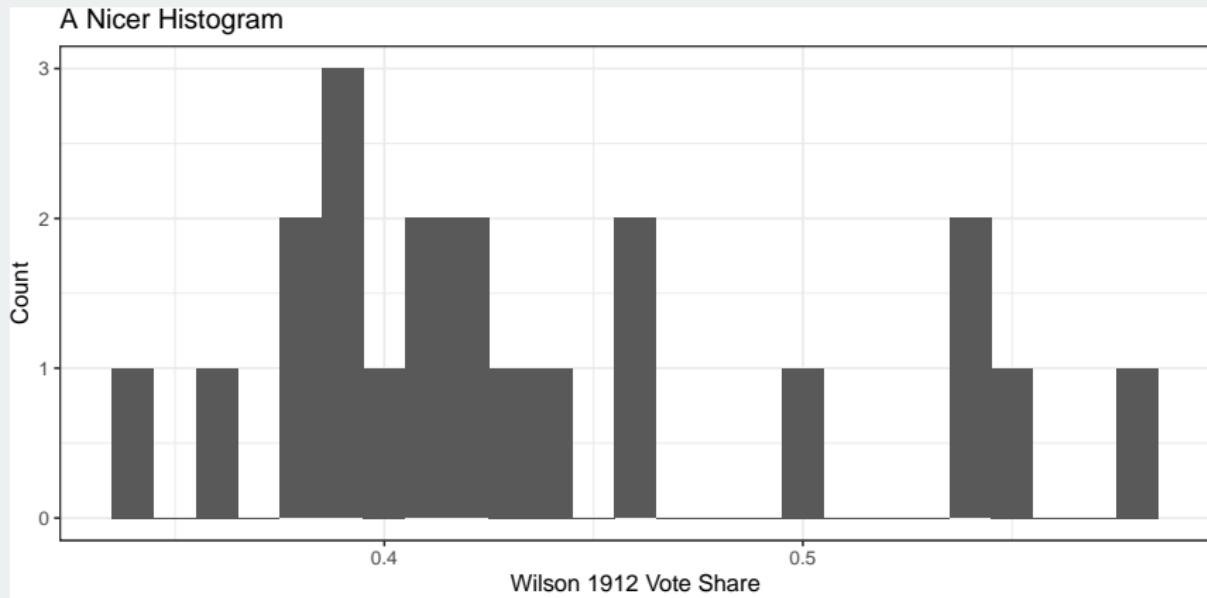

# Fancier histograms I

Not so bad. Similarly to how, with `matplotlib`, we might build up a plot with multiple method calls, here we chain function calls with the `+` operator. So we can make the histogram slightly nicer:

```
ggplot(sharks, aes(x = wilson1912)) +
  geom_histogram(binwidth = 0.01) +
  theme_bw() +
  labs(x = "Wilson 1912 Vote Share",
       y = "Count",
       title = "A Nicer Histogram")
```

# Fancier histograms II

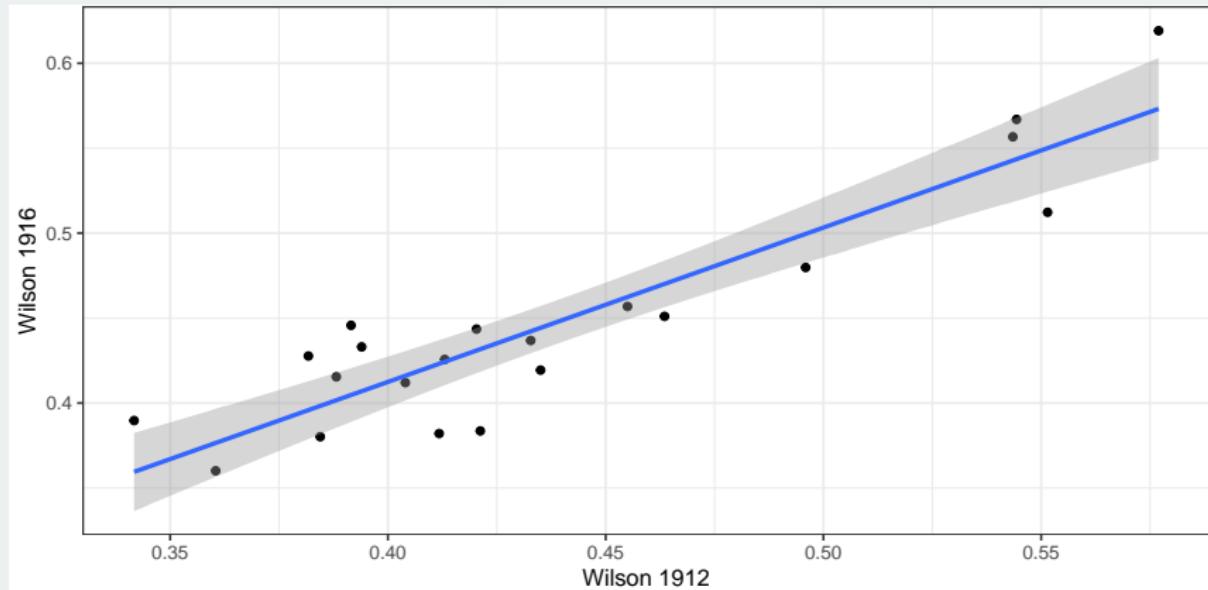

# Bivariate geoms

We can also use geoms like geom\_point or geom\_smooth to plot a bivariate relationship, like that between Wilson's 1912 and 1916 vote shares. How consistent are election returns from cycle to cycle?

```
ggplot(sharks, aes(x = wilson1912, y = wilson1916)) +  
  geom_point() +  
  geom_smooth(method = "lm") +  
  theme_bw() +  
  labs(x = "Wilson 1912",  
       y = "Wilson 1916")
```

Here we are using two geoms in one plot; there's no limitation (except pragmatic ones) on the number you can use. So we used geom\_point to draw a scatter plot and then geom\_smooth to fit a straight line summarizing those data points (the additional parameter method = "lm" indicates to use a linear model instead of the potentially nonlinear method used by default).

# Bivariate geoms II

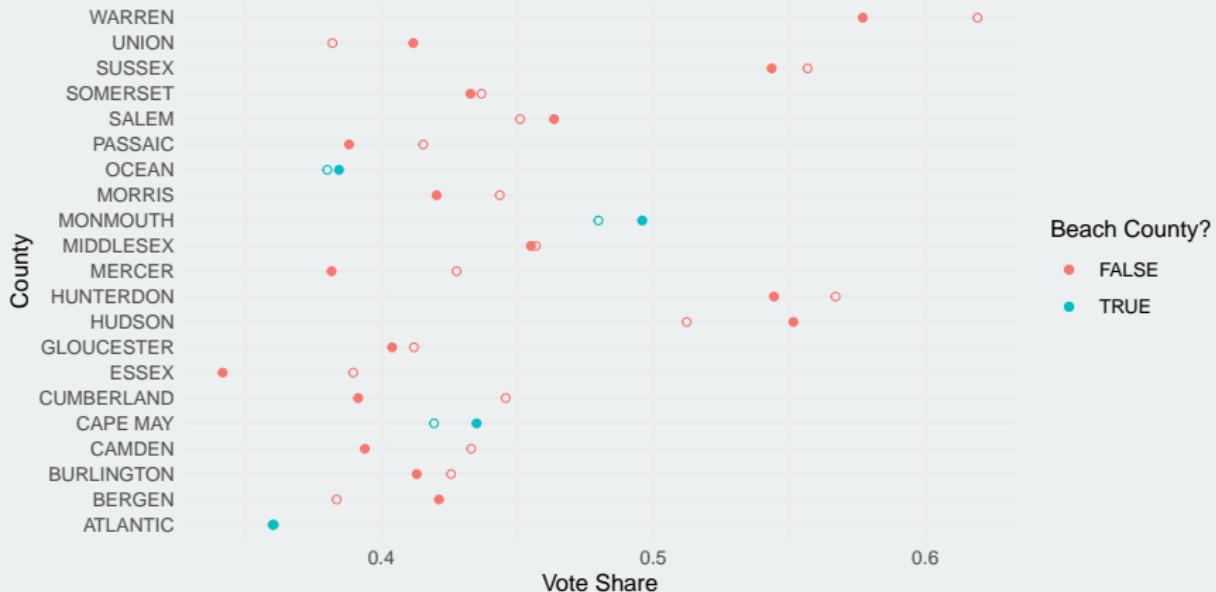

# A more complicated example I

Another way to look at this is to go county-by-county and compare.

```
ggplot(sharks, aes(y = county, color = (beach == 1))) +  
  geom_point(aes(x = wilson1912)) + # solid point  
  geom_point(aes(x = wilson1916), shape = 1) + # hollow point  
  labs(x = "Vote Share",  
       y = "County",  
       color = "Beach County?") +  
  theme_minimal()
```

# A more complicated example II

# A more complicated example III

```
ggplot(sharks, aes(y = county, color = (beach == 1))) +  
  geom_point(aes(x = wilson1912)) + # solid point  
  geom_point(aes(x = wilson1916), shape = 1) + # hollow point  
  labs(x = "Vote Share",  
       y = "County",  
       color = "Beach County?") +  
  theme_minimal()
```

Aside from showing how easy it is to build up useful visualizations, this also starts to give us some substantive insight: all of the beach counties saw either no change or a decrease in Wilson vote share; no beach county saw a meaningful increase in Wilson support. That's interesting, at least, and some (weak) evidence for the claim that voters punished Wilson for the shark attacks.

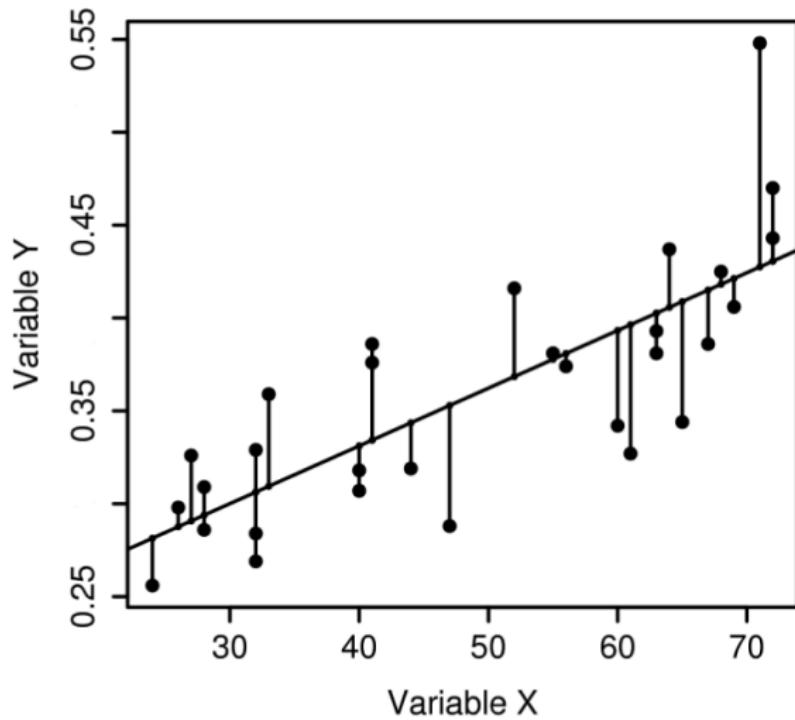

# Statistical models

What is a statistical model?

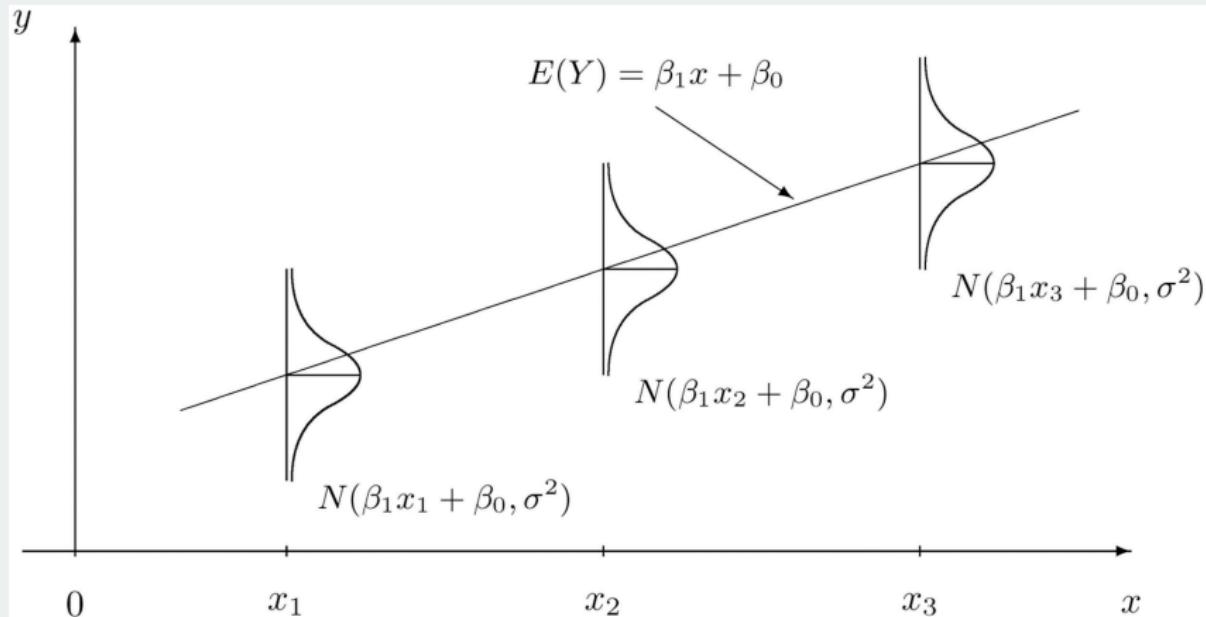

1. a probability model ( $Y_i = \beta_0 + \beta_1 x_i + \varepsilon_i$ )
2. a sampling model (independent samples from an infinite population)
3. a statistical generating mechanism (the error term is normally distributed)

# Regression

Figure 2  
OLS regression model residuals

# Regression

# An introduction to formula syntax I

Most statistical modeling functions in R use some variant of formula syntax:

```
Y ~ X
```

Often, x will include multiple variables of interest, and potentially transformations of those variables or interactions between variables.

```
Y ~ X1 + X2 + X1:X2 + I(X1^2) # transformations are nested in I()  
Y ~ X1*X2 + I(X1^2) # this expresses the same equation  
Y ~ X1*X2 + I(X1^2) - 1 # as above, but drop the intercept term
```

So, applying this to our example, we might want to regress Wilson's 1916 vote share on his 1912 vote share and see how much of the variance is explained by a simple **linear model**.

# An introduction to formula syntax II

```
m <- lm(wilson1916 ~ wilson1912, data = sharks)
```

```
summary(m)
```

```

# An introduction to formula syntax VI

# An exercise: build your own shark attack model!

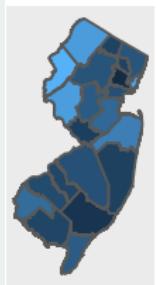

So, with all this in hand, we can start doing the sort of research that gets our name in Vox.

Ask yourself:

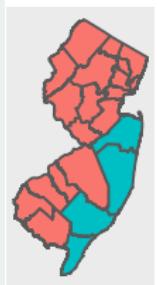

- What is the outcome of interest?
- What variables are appropriate to include?
- What would qualify as a substantively meaningful result?
- What is the interpretation of each of your coefficients?

# References on shark attacks I

Shark attacks were a big story on Political Science Twitter in summer 2018.

- Democracy for Realists (Achen and Bartels 2016) is the canonical reference for the original shark attack claim, though it was first presented at a conference over a decade earlier.
- Fowler and Hall (2018a) present a critique of the result; the data used here is drawn from their critique.
- Achen and Bartels (2018) is a response to the critique.
- Fowler and Hall (2018b) get the last word. (For now, at least.)
- Lenz (2018) wonders if this has been a good use of anyone's time.

# References on R I

## Cheat sheets

The RStudio website has some terrific cheat sheets that I encourage everyone to bookmark (especially the data wrangling one, which I have to reference every time I use `tidyR`):

- Base R
- ggplot2
- RMarkdown
- RStudio IDE
- Data Transformation

## Working in R

# References on R II

If you're doing large-scale work in R, especially involving package development, here are some useful sources on development and R internals:

- The companion website to Wickham's Advanced R book.
- The companion website to Wickham's R Packages book.

## Visualization

- Healy (2017) - Data Visualization: A Practical Introduction
- Ognyanova (2018) - Static and dynamic network visualization with R

## Workflow

# References on R III

Some good resources on structuring and approaching a data analysis project:

- **Healy (2016) - The Plain Person's Guide to Plain Text Social Science**
- Wilson et al (2017) - Good enough practices in scientific computing
- Wickham (2014) - Tidy data
- Leek (2015) - The elements of data analytic style
- The tidyverse style guide

## Networks in R

Katya Ognyanova, one of David's former postdocs, has a good introduction to network analysis in R with `igraph`.

# Code for NJ plots I

```
library(sf)
nj <- read_sf("~/Downloads/shape/New_Jersey_Counties.shp")
nj <- nj %>% left_join(sharks, by = c("COUNTY" = "county"))
```

```
p1 <- ggplot() +
  geom_sf(data = nj, aes(fill = wilson1912)) +
  coord_sf(ndiscr = 0) +
  scale_fill_continuous() +
  labs(title = "wilson1912") +
  theme(legend.position = "none")
```

# Code for NJ plots II

```
p2 <- ggplot() +
  geom_sf(data = nj, aes(fill = wilson1916)) +
  coord_sf(ndiscr = 0) +
  scale_fill_continuous() +
  labs(title = "wilson1916") +
  theme(legend.position = "none")
```

```
p3 <- ggplot() +
  geom_sf(data = nj, aes(fill = wilson1916 - wilson1912)) +
  coord_sf(ndiscr = 0) +
  scale_fill_gradient2(low = "firebrick",
                       mid = "lightgray",
                       high = "midnightblue") +
  labs(title = "change") +
  theme(legend.position = "none")
```

# Code for NJ plots III

```
p4 <- ggplot() +  
  geom_sf(data = nj, aes(fill = as.factor(attack))) +  
  coord_sf(ndiscr = 0) +  
  scale_fill_discrete() +  
  labs(title = "attack") +  
  theme(legend.position = "none")
```

```
p5 <- ggplot() +  
  geom_sf(data = nj, aes(fill = as.factor(beach))) +  
  coord_sf(ndiscr = 0) +  
  scale_fill_discrete() +  
  labs(title = "beach") +  
  theme(legend.position = "none")
```

# Code for NJ plots IV

```
p7 <- ggplot() +  
  geom_sf(data = nj, aes(fill = as.factor(machine))) +  
  coord_sf(ndiscr = 0) +  
  scale_fill_discrete() +  
  labs(title = "machine") +  
  theme(legend.position = "none")
```

```
p8 <- ggplot() +

## <matplotlib.axes._subplots.AxesSubplot object at 0x7f717af0ada0>

plt.show()
```

## Okay, but how do I do all this in Python? VIII

I guess that made Python look simpler than R...
